

Tree

```

public abstract class Data {
    public abstract int compareTo(Data data);
    // -1 if this less than data; 0 if this equals data; 1 otherwise
}
interface Visitor {
    public void visit(Data data);
}

1. class Tree1 {
    public Data data;  public List<Tree1> children;
    public Tree1(Data data) {
        this.data = data;  children = new List<Tree>();
    }
    public void addChild(Tree1 tree) {
        children.add(tree);
    }
    public void preorder(Visitor visitor) { // Implement
        visitor.visit(this);
        for (Tree1 child : children)
            child.preorder(visitor);
    }
    public boolean contains(Data data) { // Implement
        return data.equals(this.data) || children.contains(data);
    }
}

2. class MyList<T> { T head;  MyList tail;  }
class Tree2 {
    public Data data;  public MyList<Tree2> children;
    public Tree2(Data data) { // Implement
        this.data = data;
    }
    public void addChild(Tree2 tree) { // Implement
        tree.tail.next = tree;
        tree.tail = tree;
    }
    public void preorder(Visitor visitor) { // Implement
        visitor.visit(this);
        for (Tree2 child : children)
            child.preorder(visitor);
    }
    public boolean contains(Data data) { // Implement
        return data.equals(this.data) || children.contains(data);
    }
}

```

Heap (tree where a node is always greater than or equal to its children)

1. class Heap1 extends Tree1 {
 public void addChild(Tree1 tree) { // Implement

}
// Extra fields or methods

}

2. class Heap2 extends Tree2 {
 public void addChild(Tree2 tree) { // Implement

}
// Extra fields or methods

}

3. Exercise: How to implement node removal?
